INDUSTRIAL COMPLEX

HDPE FITTINGS

INNOVATION FITTINGS

ALROWAD

INDUSTRIAL COMPLEX

INNOVATION FITTINGS

Alrowad company is one of the leading Egyptian companies working in plastic industry specialized in designing and manufacturing HDPE pipes and fitting by using the best raw material and developing the highest technology and quality applied in this field, as It's production capacity reach to 6000 tons per month.

ALROWAD
INDUSTRIAL COMPLEX

HDPE FITTINGS

Alrowad company is specialized in manufacturing HDPE pipes from 32mm till 1200mm diameter with different pressure classes, It also offering welding and complementary items for polyethylene networks and supplies its machines and also train on its usage.

OUR COMPANY

also develops our products from pipes and Fitting to serve many sectors such as potable water networks, sewage water networks, infrastructure projects , natural gas, firefighting lines... etc.

Our vision

to be the leading regional manufacturers of HDPE PIPES and one of the largest manufacturers
As well as contribute in increasing the treatments of potable ,sewage and waste water in Egypt for better living

Our mission

to achieve our vision by providing our customers with Distinctive products ,reliable services ,excellence in quality through complying with both Egyptian and International standards,

CONTENT

We are providing technical support for all stages of the projects

HDPE FITTINGS

- BRASS TRANSITION FITTINGS
- FLANGES

DIFFUSERS

Wherever your project is our solution will fit

- Outfalls usually terminate in one or more diffuser sections.
- Diffusers can be of different designs such as a “Y” or “T” outlet, a pipe length in which holes have been drilled on top of the pipe within 10 and 2 o’clock, or a pipe length onto which vertical risers consisting of short sections of smaller diameter PE pipe have been fused.
- Diffusers are often designed for connection to the pipe by means of flange assemblies.
- The connection can be made prior to launching, or by divers after the pipeline has been submerged.
- When a diffuser is attached prior to launching, it is necessary to float the diffuser higher up over the water by means of some additional buoyancy.
- This is necessary to prevent water from entering the pipe through the diffuser openings.
- This additional buoyancy is released as the pipe is sunk into position.
- Extreme care should be taken in the submersion of a marine line with an engineered diffuser attached to the pipeline which is being sunk in place.
- The sinking process can create considerable stresses on the fittings that may be inherent to the de- sign of the diffuser itself such as flanges, tees and/or other mechanical connections.

APPLICATION AND INSTALLATION HDPE PIPES

APPLICATION AND INSTALLATION HDPE PIPES

PREPARATION OF TRENCH BOTTOM:

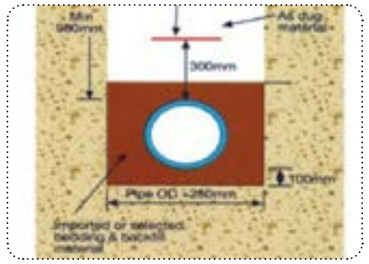
- The trench bottom should be
constructed to prove a firm, stable and uniform support from the full length of the pipe
- When an unstable sub-grade condition is encountered which will provide inadequate pipe support, additional trench depth should be excavated and refilled with suitable foundation materials as specified by the engineer
- The ground water level in the trench should be kept below the pipe

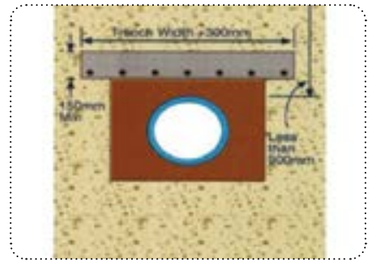
BEDDING:

Bedding is required primarily to bring the trench bottom up to grade.
- Bedding materials should be placed to provide a uniform and adequate longitudinal support under the pipe.
- A compacted depth of 4 to 6 inches (100-150mm) is generally sufficient bedding thickness.
- Bedding material should be free of ridges, hollows and lumps.
- The trench bottom should be smooth and free of rocks.
- Bedding should consist of free flowing material such as gravel, sand, salty sand or clayey sand that is free of stones or hard practices larger than 1 1\2 inch.

HAUNCHING:

The most important factor affecting the pipe performance and deflection is the haunching material and its density
- Material should be placed and consolidated under the pipe haunch to provide adequate side support to the pipe while avoiding both vertical and lateral displacement of the pipe from proper alignment.
- Where coarse material with voids has been used for bedding, the same coarse material should also be used for haunching and consideration should be given to native soil migration.
- Haunching is placed up to the pipe spring line.





INITIAL BACKFILL:

Initial backfill is that portion of the pipe embedment beginning at the spring line of extending some distance over the pipe and the top of the pipe.
- Since no additional side support is gained above the spring line, native soil may be used without special compaction efforts.
- The sole purpose of somewhat careful placement of these native trench materials is to protect the pipe from the dropping of large rocks or other impact loads that may occur during final backfill
- Minimum cover is recommended to be 6 inch (150mm)

FINAL BACKFILL:

The material used in the final backfilling operation need not to be as carefully selected as the bedding, haunching and the initial backfill material, exclude boulders, frozen clumps of dirt, and rubble which could damage the pipe.

QUALITY ASSURANCE AND FIELD TESTING:

LEAK TESTING - CONSIDERATIONS FOR ALL PROCEDURES

The intent of leak testing is to find unacceptable joint leakage in pressure piping systems. If leaks exist, they may manifest themselves by leakage or rupture. Leak tests of pressure systems generally involve filling the system or a section of the system with a liquid or gaseous fluid and applying internal pressure to determine resistance to leakage.

Safety is of paramount importance when conducting pressurized internal fluid leak tests. Although routinely performed, leak tests may be the very first time a newly installed system or repair will be subjected to stress.

- Even at relatively low internal pressures, leak testing with a pressurized internal fluid can generate very high forces that can be dangerous or even fatal if suddenly released by the failure of a joint or system component or a testing component.
- Always take safety precautions when conducting pressurized fluid leak tests.
- Restrain pipe, components and test equipment against movement in the event of failure. Joints may be exposed for leakage inspection provided that restraint is maintained.
- Keep persons not involved in testing a safe distance away while testing is being conducted.
- Liquids such as water are preferred as test fluids because less energy is released if something in the test section fails catastrophically. During a pressure leak test, energy (internal pressure) is applied to stress the test section. If the test fluid is an incompressible liquid such as water, the energy applied to pressurize the liquid transfers primarily to the pipe and components in the test section. However, if the test fluid is a compressible gas, energy is applied to compress the gas as well as to stress the piping section. If a catastrophic failure occurs during a pressurized liquid leak test, the overall applied energy is much lower and energy dissipation is rapid.
- However, if catastrophic failure occurs during a pressurized gas test, energy release is many times greater, much more forceful and longer duration.
- Where hydrostatic testing is specified, never substitute compressed gas (pneumatic) for liquid (hydrostatic) testing.
- Maximum leak test pressure is temperature dependent. If possible, test fluid and test section temperatures should be less than 80°F (27°C). At temperatures above 80°F (27°C), reduced test pressure is required. Contact the pipe manufacturer for technical assistance with elevated temperature pressure reduction. Sunlight heating of exposed PE pipe, especially black PE pipe, can result in high pipe temperature.

- Before applying test pressure, allow time for the test fluid and the test section to temperature equalize. Hydrostatic leak tests typically use cooler liquids so the liquid-filled test section will tend to equalize to a lower temperature near test liquid temperature. Compressed gases used in pneumatic leak tests do not have similar temperature lowering eqects, so it is more likely that test pressures will have to be reduced due to elevated temperature eqects when conducting pneumatic leak tests. Bursting can result if test pressure is not reduced for elevated test section temperature.
- Leak Test Pressure and Duration – The maximum allowable leak test pressure and leak test time including initial expansion, and time at leak test pressure should be in accordance with the following equation and Tables 12 and 13.

$$PI_{(T)} = \frac{2 \times HDS \times F_t \times H_T}{(DR-1)}$$

Where:
$P_{(T)}$ = Leak Test Pressure, psig, for Leak Test Time, T (from Table 11)
T = Leak Test Time, hours
HDS = PE material hydrostatic design stress for water at 73°F (23°C), psi
F_t = PE material elevated temperature reduction factor
H_T = Leak test duration factor for leak test time, T
DR = Pipe dimension ratio

Table 12: Leak Test Duration Factor, H_T

Leak Test Pressure $P_{(T)}$ (psig)	Leak Test Time T(hours)	Leak Test Duration Factor H_T
$P_{(8)}$	≤8	1.5
$P_{(48)}$	≤48	1.25
$P_{(120)}$	≤120	1.00

Table 13: PE Material Hydrostatic Design Stress (HDS)

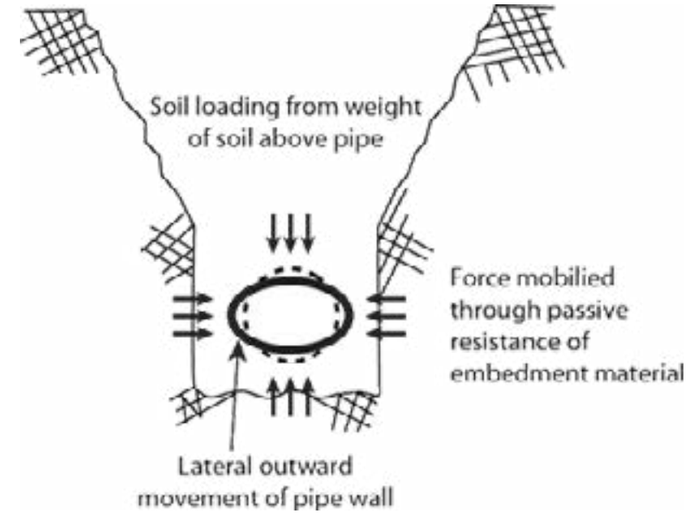
PE Material Designation Code	HDS for Water at 73°F (psi)
PE2708	800
PE3608	800
PE3710	1000
PE4710	1000

ENGINEERED TRENCH SPECIFICATION:

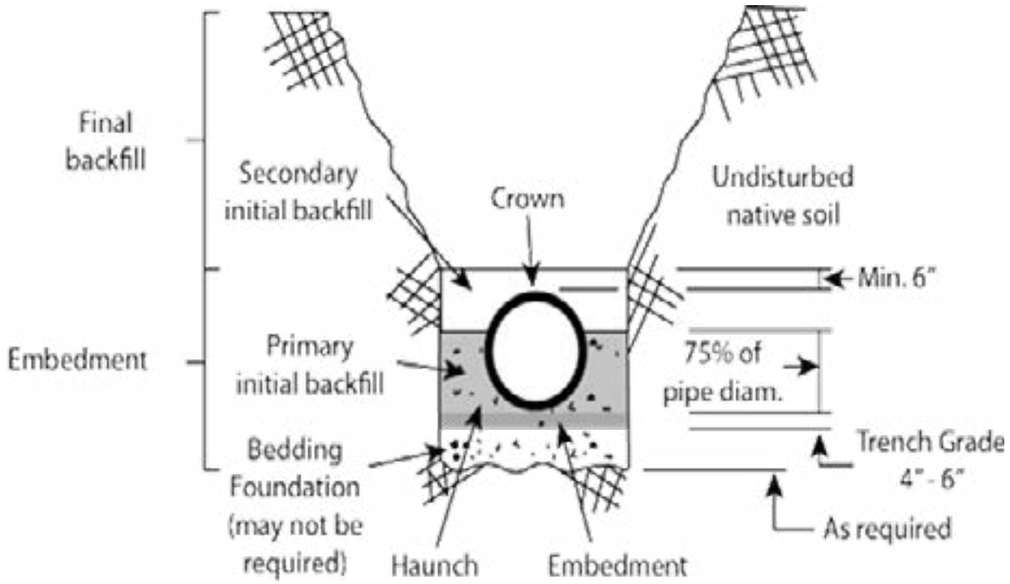
For applications where the simplified installation guidelines do not apply -- such as gravity flow pipes that are relatively deep, shallow cover applications where the pipe is subject to vehicular or train loading, pipes placed in unstable, soft, or wet soils, high DR pipes, or pipes in deep applications such as landfills and embankments -- the engineer must prepare a specific embedment specification. In these cases, detailed attention must be paid to the native soil, the embedment soil, and the placement of the embedment soil. The key objective of installation is to minimize or control subsequent pipe deflection. A limit of 5% is commonly used, which provides an additional safety factor, as most gravity flow PE pipe can withstand higher deflection without damage.

The load carrying capability of a PE pipe, particularly a pipe with a high DR, can be greatly increased by the soil in which it is embedded, including the installation procedure. When the pipe is loaded, load is transferred from the pipe to the soil by a horizontal outward movement of the pipe wall. This enhances contact between pipe and soil and mobilizes the passive resistance of the soil. This resistance aids in preventing further pipe deformation and contributes to the support for the vertical loads.

The factors to be considered in a properly engineered installation specification include pipe embedment materials, compaction of embedment materials, trench dimensions, and trench design and construction. These four items are discussed separately



Mobilization of Enveloping Soil through Pipe Deformation



PE piping is considered “flexible”, indicating such products can withstand large amounts of deflection without damage. However, since their flexibility is directly proportional to the dimension ratio (outer diameter divided by minimum wall thickness), diaerent installation requirements may be necessary for diaerent DR values to achieve successful and economical installations. The depth of cover and anticipated surface loads aaect the particular installation requirements. Therefore, the engineer has to make an assessment of the application and site conditions to determine the best and most economical installation design.

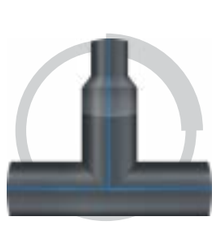
There are two objectives to achieve in an installation. The first is to provide an envelope of embedment to protect the pipe from mechanical damage from impact or hard objects (cobbles, boulders) in the soil. The second is to provide support against earth and live load pressures, where required. The earth and live loads are supported by the combination of the stianess of the pipe and the stianess of the surrounding embedment material. Lower DR pipes will carry more of the load and require less support from the soil in haunch areas. When support from the embedment is needed by the pipe to resist earth and live loads, the embedment material is often compacted. The trench backfill placed on top of the embedment material may also be compacted. Compaction of trench backfill immediately above the pipe facilitates the redistribution of some of the load away from the pipe and into the side-fill soil.

FABRICATED FITTINGS

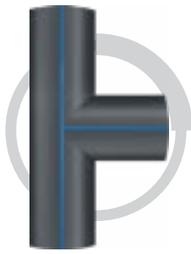
1200-110 mm
Welding procedures

HDPE FITTINGS
WELDING FITTINGS:

Butt welding method used to join two lengths of PE pipes together or join PE pipe with PE fitting This method conform to DVS 2207-1
Polyethylene (PE) pipes for the production of butt fusion joints in accordance with this method shall conform to ISO 4437, ISO4427-2 , DIN8074/8075 or equivalent standards.



Segmented Reduced Tee 90°
From 110mm - 630mm



Segmented Tee 90°
From 90mm - 630mm

Segmented Cross
From 110mm - 630mm

Segmented Tee 90°
From 110mm - 120mm

Segmented Tee 60°
From 110mm - 1200mm

Segmented Tee 45°
From 110mm - 1200mm

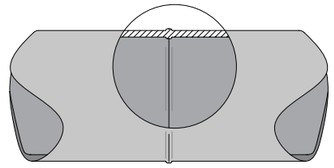
Segmented Tee 30°
From 110mm - 1200mm

HDPE FABRICATED FITTINGS

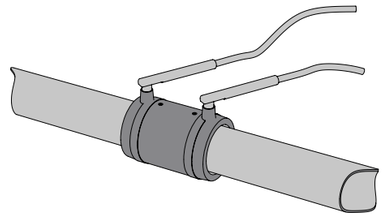
JOINTING :

One of the greatest features of HDPE pipes is the fact that a wide variety of jointing systems is available to suit a whole range of applications. The jointing systems can be divided into permanent jointing and detachable jointing. The schematic below illustrates the available systems.

PERMANENT JOINTING :



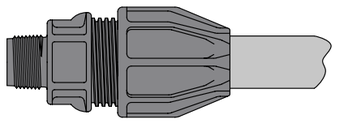
- Buttwelding -



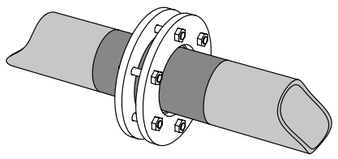
- Electro-fusion -

“Both buttwelding and elec tro-fusion systems allow transition to detachable joints”.

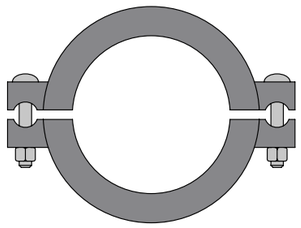
NON-PERMANENT (DETACHABLE) JOINTING :



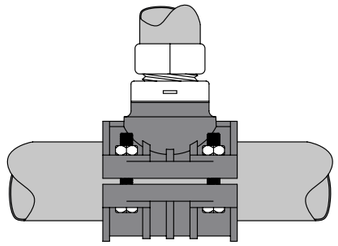
- Compression Fittings* -



- Flanging -



- Tak System -



- Magnum Saddles and Holderbats** -

* : “ Refer to our Marley Astore Compression Fittings document for full details on these products.”
** : “ Refer to our Magnum saddles and Holderbats document for full details on these products. “

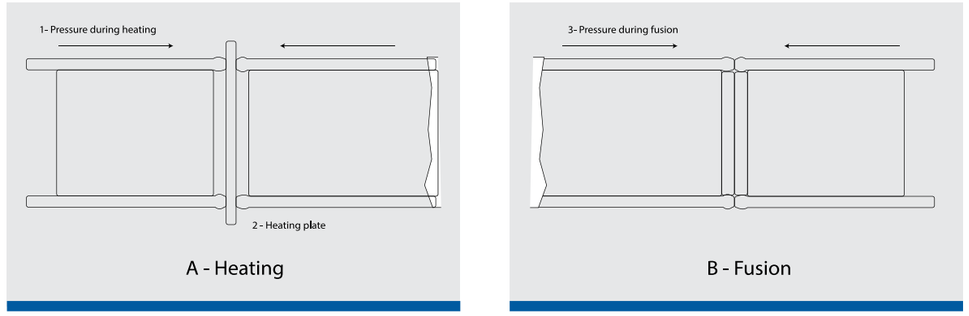
BUTT WELDING :

BUTT FUSION WELDING :

Butt welding method used to join two lengths of PE pipes together or join PE pipe with PE fitting
This method conform to DVS 2207-1
Polyethylene (PE) pipes for the production of butt fusion joints in accordance with this method shall conform to ISO 4437, ISO4427-2 , DIN8074/8075 or equivalent standards.

BUTT FUSION PRINCIPLE :

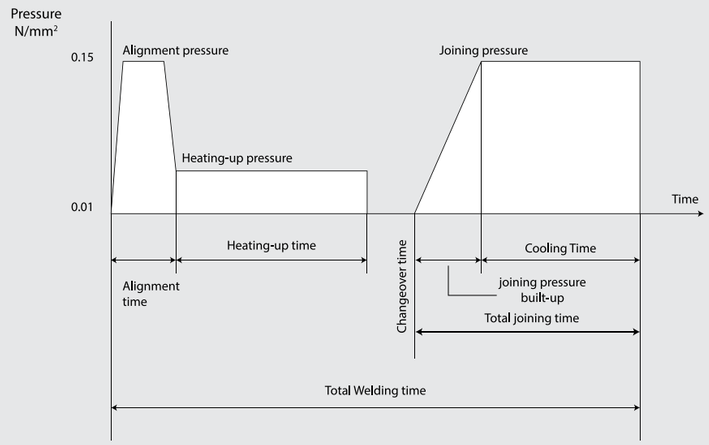
The principle of butt fusion jointing is to heat two pipes or fitting ends by means of a heater plate to a designated temperature, then fuse them together by applying pressure and cool them under pressure for a designated time. Butt fusion joints shall be made by qualified oper- ators using butt fusion jointing ma- chines that secures and precisely align the pipe ends.



Butt Fusion Principles

BUTT FUSION WELDING MACHINE:

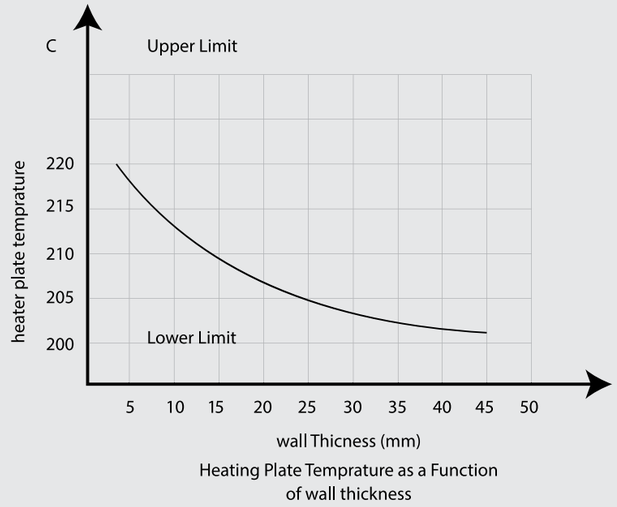
The following conditions should be achieved in a butt welding machine. Aligning the pipe ends. Clamping the pipes. Facing the pipe ends parallel and square to the centerline. Heating the pipe ends. Applying the proper fusion force. Conforming to ISO12176-1, DVS2208-1



Butt Fusion Cycle

BUTT FUSION TEMPERATURE:

The butt fusion temperature is normally situated between 200 c and 220 c



Heating Plate Temprature as a Function of wall thickness

BUTT FUSION JOINTING PROCEDURE:

The following steps should be executed to make perfect butt welding:
- Clean the pipe or fitting ends, planning unit or heater's surfaces
- Clean the inside and the outside of the pipe or fitting to be joined by wiping the joint area with a clean lint-free cloth
- All foreign matter should be removed from the jointing area
- Clean the planning unit and the heater plate surfaces with a clean lint-free cloth
- Ensure the heater is cold and the power to unit is off
- It is recommended that two dummy joints be made at the start of each jointing session to ensure removal of fine contaminated particles whenever the heater plate has been allowed to cool below 180 c or for a size change.

CLAMP AND ALIGNED THE COMPONENTS TO BE JOINED:

- Clamp the components in the butt fusion jointing machine and adjust as necessary to achieve prop-er alignment.

PLANNING THE PIPE OR FITTING ENDS:

- Plane the pipe or fitting ends to establish clean, parallel mating surfac-es

ALIGN THE PIPE OR FITTING ENDS:

- Remove any shavings from the pipe or fitting ends
- Inspect the pipe or fitting ends for incomplete planning, voids or other imperfections then bring them to-gether to check for proper alignment.
- The permissible gap width between pipe or fitting ends under alignment pressure is described in the fol-lowing table

Pipeoutside diameter(mm)	Gap width (mm)
≤335	0.5
400....< 630	1
630....<800	1.3
800....<1000	1.5
>1000	2

MEASURING THE DRAG AND COMPENSATING PRESSURE ACCORDINGLY:

Measure the gauge pressure required to overcome
the frictional drag of the machine and pipe
This pressure shall be added to the calculated bead-up and fusion jointing pressure.

MELT THE PIPE OR FITTING INTERFACES:

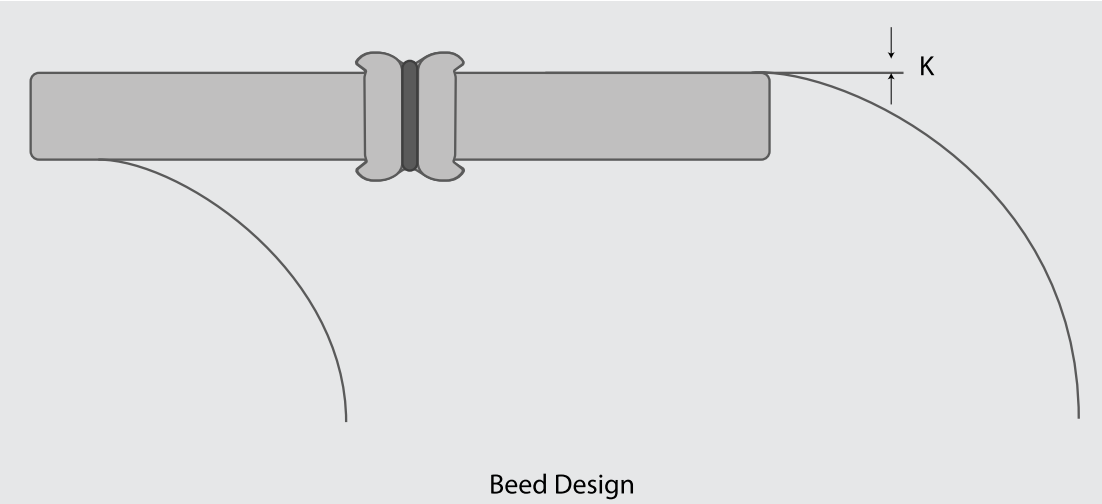
The surface of the heater plate that comes into contact with the pipe or fitting ends shall be clean, oil-free and coated with non-stick coating to prevent molten plastic from adhering to the heater plate surface.
Install the heater plate in the butt fusion machine and bring both of pipes or fitting ends simultaneously into full contact with the heater plate to produce molten surface for fusion jointing.
To ensure that full contact is made between the pipe or fitting ends and the heater plate , the initial contact shall be made under Alignment pressure (0.15Mpa). after holding the pressure until a specified bead height has formed, the pressure shall be adjusted to the heating-up pressure (≤0.02 MPa) without breaking contact between the heater plate and the pipe or fit- ting ends for a period equal to the hating-up time.

JOIN THE TWO PIPE OR FITTING ENDS TOGETHER BY APPLYING THE PROPER FUSION FORCE:

On completion of the heat soak time, pull the pipe or fitting ends from the heater plate. Then remove the heater plate and bring the molten pipe or fitting ends together within the specified time (changeover time). The joint shall be held at the jointing pressure (0.15 MPa) for a prescribed fusion jointing time (bulid-up time)

HOLD UNDER PRESSURE UNTIL THE JOINTS IS COOL:

The molten joint shall be held immobile under pressure in the butt fusion jointing machine for a period of time defined as the cooling tome in the machine under pressure. Allowing adequate time for cooling un-der pressure prior to removal from machine clamps is import- ant in order to develop strength and achieve joint integrity. Further cooling may take place in the machine without pressure or out of the machine, partic-ularly if working in high ambient temperatures.



Beed Design

PARAMETERS AND VALUES FOR FUSION JOINTING PROCEDURE

Heater Plate temperature °C	Alignment Pressure (Mpa)	Heating up Pressure (Mpa)		Jointing Pressure (Mpa)
